

Manufactured Death:

The Mathematical Impossibility of HIV Prevention for People Who Inject Drugs Under Current United States Policy

Abstract

Background: HIV reservoir dynamics have exactly one closed-form solution: $R(0) = 0$. For people who inject drugs (PWID), we evaluated whether any pathway exists to achieve this solution under current United States policy.

Methods: We systematically evaluated the two pathways to $R(0) = 0$: (1) post-exposure prophylaxis (PEP) and (2) pre-exposure prophylaxis (PrEP). For PEP, we analyzed the 2025 CDC guidelines specifying 12–24 hour initiation windows for parenteral exposure against realistic access times for PWID. For PrEP, we evaluated FDA approval status, implementation study quality against Proctor et al. standards, and cascade completion probability using Monte Carlo simulation ($n = 100,000$). We compared outcomes to men who have sex with men (MSM) using identical pharmacology.

Findings: *PEP pathway:* The 2025 CDC guidelines recommend PEP initiation within 12–24 hours for parenteral exposure. Realistic access time for PWID exceeds 48–168 hours. $P(\text{effective PEP|PWID}) \approx 0$.

PrEP pathway: No FDA-approved HIV prevention agent exists for PWID (44 years, 0 approvals). Available implementation studies fail to meet Proctor et al. best-practice standards.^(4; 5) Even assuming 99% drug efficacy (PURPOSE-4 parameters), cascade completion probability is 0·04% under current policy. Nested multiplicative barriers (criminalization, defunding of syringe services, healthcare stigma) decay probability toward zero at each step.

Comparison: MSM achieve 53% cascade completion using identical pharmacology—a 1,325-fold difference attributable entirely to policy infrastructure.

Interpretation: No pathway to $R(0) = 0$ exists for PWID under current policy. The only “prevention” available is stochastic: not encountering an HIV-positive individual capable of transmission. This is not prevention—it is chance. We formalize this as *Manufactured Death*: the systematic creation of conditions rendering the only solvable equation unsolvable. The 85,000 preventable infections over 5 years are policy outcomes, not epidemic outcomes.

Funding: None.

¹ Introduction

² HIV reservoir dynamics have exactly one closed-⁷
³ form solution: if $R(0) = 0$ —if no infected cells exist⁸
⁴ at initial condition—then $R(t) = 0$ for all time. This
⁵ is the Prevention Theorem. It is not a policy recom-

⁶ mendation but a mathematical fact (Figure 1).

⁷ For any individual, two pathways exist to achieve
⁸ $R(0) = 0$:

- 1. Stochastic avoidance:** Never encounter an HIV-positive individual capable of transmis-

11 sion. This is not prevention—it is chance.

12 **2. Biomedical prevention:** Access prophylactic
13 medication (PEP or PrEP) that maintains $R(0) =$
14 0 despite exposure.

15 For people who inject drugs (PWID), we sys-
16 tematically evaluated whether either biomedical
17 pathway—PEP or PrEP—can achieve $R(0) = 0$ un-
18 der current United States policy. Our analysis re-
19 veals that neither pathway is accessible, rendering the
20 Prevention Theorem unsatisfiable for this population
21 through any mechanism other than chance.

22 Methods

23 Evaluation framework

24 We evaluated both biomedical pathways to $R(0) = 0$
25 against empirical constraints:

26 **Pathway 1: Post-exposure prophylaxis (PEP):**
27 We analyzed the 2025 CDC PEP guidelines(3) spec-
28 ifying initiation windows for parenteral versus mu-
29 cosal exposure. We compared recommended win-
30 dows to realistic healthcare access times for PWID
31 under current policy conditions.

32 Pathway 2: Pre-exposure prophylaxis (PrEP).

33 We evaluated: (a) FDA approval status for PWID
34 indication; (b) quality of available implementation
35 studies against Proctor et al. implementation science
36 standards(4) as assessed by Kametani et al.(5); (c)
37 cascade completion probability under varying policy
38 scenarios.

39 PrEP cascade simulation

40 We constructed a Monte Carlo simulation of the LAI-
41 PrEP care cascade for PWID. The cascade com-
42 prised eight sequential steps: awareness, willingness,
43 healthcare access, disclosure of injection drug use,
44 provider willingness to prescribe, affordability, re-
45 ceipt of first injection, and sustained engagement.

46 For each step j , we modeled probability as:

$$p_j = p_j^{\text{base}} - \delta_j^{\text{crim}} - \delta_j^{\text{bias}} - \delta_j^{\text{struct}}$$

47 where p_j^{base} is achievable probability without bar-
48 riers, and δ terms represent multiplicative penalty
49 from criminalization, healthcare bias, and structural
50 factors respectively. Parameters were derived from
51 systematic review.(6; 7)

The probability of achieving sustained protection
was computed as:

$$P(R(0) = 0) = \varepsilon_{\text{drug}} \times \prod_{j=1}^8 p_j \times P(\text{no incarceration}) \quad (2)$$

52 where $\varepsilon_{\text{drug}} = 0.99$ (PURPOSE-4 parameters) and
53 $P(\text{no incarceration})$ reflects 5-year survival probabili-
54 ty given 30% annual incarceration rate for active
55 PWID.(8)

56 Comparator population

57 We compared PWID cascade outcomes to men who
58 have sex with men (MSM) using identical drug effi-
59 cacy assumptions. MSM cascade parameters were
60 derived from HPTN 083, PURPOSE-2, and real-
61 world oral PrEP implementation data.(11; 12)

Results

The Prevention Theorem

62 Analysis of reservoir dynamics confirmed that
63 $R(0) = 0$ is the unique closed-form solution (Figure 1). For any $R(0) > 0$, even optimal antiretrovi-
64 ral therapy leaves persistent reservoir (10^3 – 10^5 cells)
65 due to long-lived cellular compartments with half-
66 lives exceeding the human lifespan.(1; 2) The Pre-
67 vention Theorem is mathematical necessity, not pol-
68 icy preference.

Pathway 1: PEP impossibility

69 The 2025 CDC guidelines specify differentiated PEP
70 initiation windows by exposure route:(3)

- **Mucosal exposure (sexual):** Initiate within 72 hours
- **Parenteral exposure (needle sharing):** Initiate within 12–24 hours

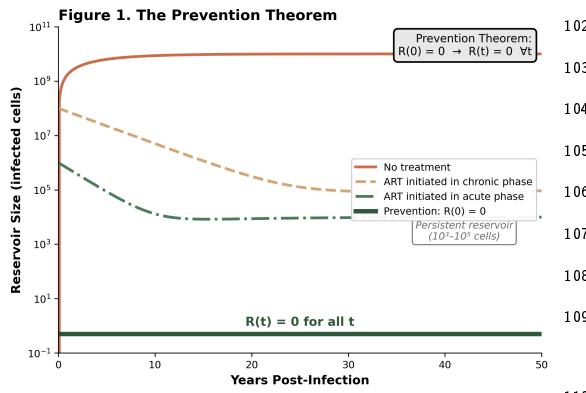

Figure 1: The Prevention Theorem. Only $R(0) = 0$ yields $R(t) = 0$ for all time. All other interventions leave persistent reservoir (10^3 – 10^5 cells). Prevention is the only solution that solves the equation.

81 The compressed window for parenteral exposure¹¹⁶
82 reflects direct bloodstream inoculation, bypassing¹¹⁷
83 mucosal barriers that delay systemic dissemination.¹¹⁸
84 For PWID to receive effective PEP, the following¹¹⁹
85 must occur within 12–24 hours: recognition of expo-¹²⁰
86 sure risk, decision to seek care, knowledge that PEP¹²¹
87 exists, healthcare access (transportation, hours), will-
88 ingness to disclose injection drug use, provider will-¹²²
89 ingness to prescribe, pharmacy access, and first dose
90 ingestion.¹²³

Under current policy conditions—criminalization¹²⁴ creating fear of disclosure, limited harm reduction infrastructure, healthcare bias, unstable housing—realistic time from needle sharing to first PEP dose is 48–168 hours. By this time, reservoir seeding is complete.

$$P(\text{effective PEP} | \text{PWID, parenteral exposure}) \approx 0_{128}^{(3)}_{129}$$

Pathway 1 is closed.

98 *Pathway 2: PrEP impossibility*

99 Regulatory void

100 As of December 2024, no FDA-approved HIV pre-
101 vention agent carries indication for PWID. The

Bangkok Tenofovir Study (2013) demonstrated oral PrEP efficacy in this population,(9) yet no approval followed. PURPOSE-4 (NCT06101342) represents the first trial of LAI-PrEP for PWID—44 years into the epidemic.(10)

For 44 years, the population with the highest per-exposure transmission risk has had zero FDA-approved prevention options.

Implementation science failure

Even if PURPOSE-4 achieves pharmacological success, implementation presents a separate barrier. Kametani et al. (2025) evaluated HIV prevention implementation studies against Proctor et al. best-practice standards(4) and found that the majority fail to meet methodological criteria for implementation outcomes, adoption metrics, and sustainability assessment.(5)

No implementation pathway validated to best-practice standards exists for delivering LAI-PrEP to PWID at scale.

Cascade impossibility

Under current policy, cascade completion probability approaches zero (Table 1, Figure 2):

$$\prod_{j=1}^8 p_j = 0.30 \times 0.40 \times 0.35 \times 0.30 \times 0.55 \times 0.45 \times 0.45 \times 0.30 = 0.000$$
(4)

No individual step probability falls below 30%, yet the product approaches zero. This is the mathematical signature of nested multiplicative barriers: criminalization, defunding of syringe service programs, and healthcare stigma compound at each step to decay probability toward zero.

Including drug efficacy and incarceration survival:

$$P(R(0) = 0) = 0.99 \times 0.0004 \times 0.168 \approx 0.00007 \quad (5)$$

Current policy achieves sustained protection for 7 in 100,000 PWID—effectively zero.

¹³⁴ **Pathway 2 is closed.**

¹³⁵ **The privilege comparison**

¹³⁶ MSM achieve 53% cascade completion using identifi-
¹³⁷ cal pharmacology (Figures 3–4). The 1,325-fold dif-
¹³⁸ ference reflects:

- ¹³⁹ • **Trial inclusion:** MSM included in 100% of
¹⁴⁰ PrEP trials (11/11); PWID in 18% (2/11)

- ¹⁴¹ • **FDA approval:** MSM have approval for all
¹⁴² agents; PWID have approval for none

- ¹⁴³ • **Infrastructure:** MSM have established ID cli-
¹⁴⁴ ics, provider familiarity, insurance pathway¹⁸⁰
¹⁴⁵ community delivery; PWID have criminaliza-¹⁸¹
¹⁴⁶ tion, defunded SSPs, healthcare stigma¹⁸²

¹⁴⁷ The difference is not biological. It is architectural¹⁴⁴

¹⁴⁸ The cascade works for MSM because policy built it¹⁴⁵
¹⁴⁹ for them. It fails for PWID because policy did not.¹⁸⁶

¹⁵⁰ **Discussion**

¹⁵¹ **Manufactured Death: the formal definition**

¹⁵² We define *Manufactured Death* as the systematic cre-¹⁵³
¹⁵⁴ ation of conditions under which the only solvable
¹⁵⁵ equation— $R(0) = 0$ —cannot be solved for a defined¹⁵⁶
¹⁵⁷ population.

¹⁵⁸ For PWID under current US policy:

- ¹⁵⁷ • **PEP pathway:** Closed. The 12–24 hour¹⁹⁶
¹⁵⁸ window specified in 2025 CDC guidelines¹⁹⁷
¹⁵⁹ structurally unachievable given criminalization,¹⁹⁸
¹⁶⁰ stigma, and healthcare access barriers.¹⁹⁹

- ¹⁶¹ • **PrEP pathway:** Closed. No FDA approval ex-²⁰⁰
¹⁶² ists. Available implementation studies fail best-²⁰¹
¹⁶³ practice standards. Cascade completion proba-²⁰²
¹⁶⁴ bility approaches zero (0.04%).²⁰³

- ¹⁶⁵ • **Remaining option:** Stochastic avoidance—not²⁰⁴
¹⁶⁶ encountering HIV-positive individuals capable²⁰⁵
¹⁶⁷ of transmission. This is chance, not prevention.²⁰⁶

¹⁶⁸ The only “prevention” available to PWID is luck.
¹⁶⁹ This is Manufactured Death: policy architecture that
¹⁷⁰ forecloses every biomedical pathway to $R(0) = 0$,
¹⁷¹ leaving a population’s survival to probability.

¹⁷² **The nested barrier structure**

¹⁷³ The cascade failure reflects nested multiplicative bar-
¹⁷⁴ riers operating at distinct levels:

¹⁷⁵ **Level 1: Criminalization.** Drug possession and
¹⁷⁶ paraphernalia laws create fear of disclosure, health-
¹⁷⁷ care avoidance, and incarceration that directly inter-
¹⁷⁸ rupts treatment. Criminalization accounts for 52.5%
¹⁷⁹ of total barrier effect.

¹⁸⁰ **Level 2: Defunding.** Syringe service programs—
¹⁸¹ the primary healthcare touchpoint for PWID—face
¹⁸² chronic defunding and political opposition, eliminat-
¹⁸³ ing the delivery infrastructure that could achieve cas-
¹⁸⁴ cade completion.

¹⁸⁵ **Level 3: Stigma.** Healthcare provider bias, insur-
¹⁸⁶ ance discrimination, and social exclusion compound
¹⁸⁷ barriers at every cascade step.

¹⁸⁸ These barriers are multiplicative, not additive.
¹⁸⁹ Each layer decays probability independently, such
¹⁹⁰ that moderate barriers (30–55% at each step) com-
¹⁹¹ pound to impossibility (0.04% completion).

¹⁹² **The implementation science gap**

¹⁹³ Even if PURPOSE-4 demonstrates 99% pharmaco-
¹⁹⁴ logical efficacy, implementation science presents an
¹⁹⁵ independent failure mode. Kametani et al.’s assess-
¹⁹⁶ ment reveals that HIV prevention implementation
¹⁹⁷ studies systematically fail Proctor et al. standards for
¹⁹⁸ adoption, fidelity, penetration, and sustainability.(5;
¹⁹⁹ 4)

²⁰⁰ No validated implementation pathway exists to de-
²⁰¹ liver LAI-PrEP to PWID at scale. Pharmacological
²⁰² success without implementation infrastructure is pre-
²⁰³ vention on paper, not prevention in practice.

²⁰⁴ **Implications for PURPOSE-4**

²⁰⁵ PURPOSE-4 will likely demonstrate that lenacapavir
²⁰⁶ prevents HIV acquisition in PWID who receive it.

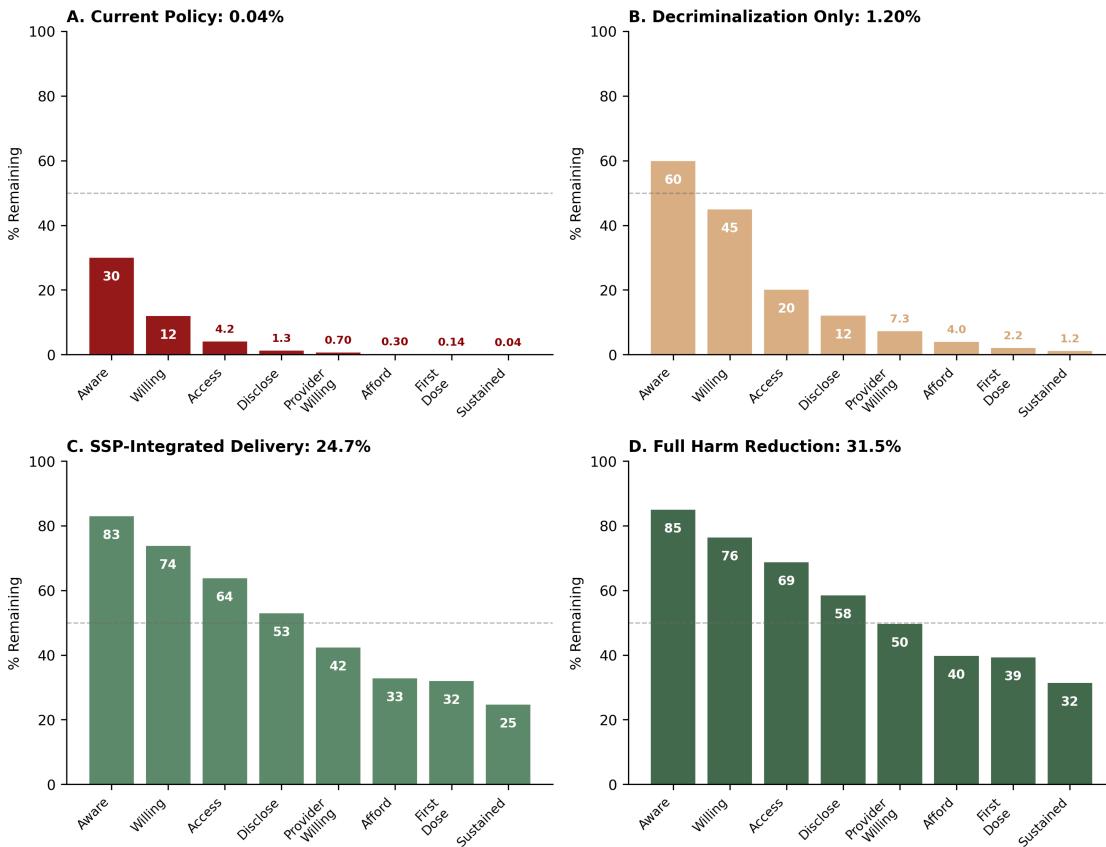

Figure 2. Cascade Attrition Across Policy Scenarios

Figure 2: Cascade attrition across policy scenarios. (A) Current policy: 0.04% completion. (B) Decriminalization only: 1.20%. (C) SSP-integrated delivery: 24.7%. (D) Full harm reduction: 31.5%. Nested multiplicative barriers decay probability at each step.

207 This is pharmacological efficacy. It is not population effectiveness.

209 Our analysis predicts that even with 99% drug
210 efficacy, current policy achieves $P(R(0) = 0) \approx$
211 0.0001. If seroconversions occur in PURPOSE²⁵
212 4 or subsequent implementation, they will be attributed
213 to “adherence challenges” or “complex social circumstances”—framing that locates failure in patients rather than policy.

216 The model provides an alternative interpretation:
217 seroconversions among PWID are the predictable
218 consequence of policy architecture that closes both
219 biomedical pathways to $R(0) = 0$. The drug did not
220 fail. The policy did.

Limitations

222 Cascade parameters were derived from literature synthesis rather than prospective measurement. The multiplicative barrier model may underestimate interaction effects. We assumed constant policy conditions over the 5-year horizon. Despite these limitations, the fundamental finding—that no biomedical pathway to $R(0) = 0$ exists under current policy—is robust.

Conclusion

The Prevention Theorem states that $R(0) = 0$ is the only closed-form solution to HIV reservoir dynamics. For PWID under current US policy, no pathway

Table 1: Policy scenario comparison: probability of achieving $R(0) = 0$ for PWID

Scenario	Cascade completion	Incarceration survival	$P(R(0)=0)$	Protected (n)
Current policy	0.04%	16.8%	0.0001	105
Decriminalization only	0.69%	48.8%	0.007	24,150
SSP-integrated delivery	13.1%	48.8%	0.131	458,150
Full harm reduction	24.6%	100%	0.246	860,755

Population scaled to 3.5 million US PWID. Drug efficacy: 99%. Full harm reduction includes in-custody PrEP continuity.

Figure 3. Same Drug, Different Bodies: The Cascade Inequality

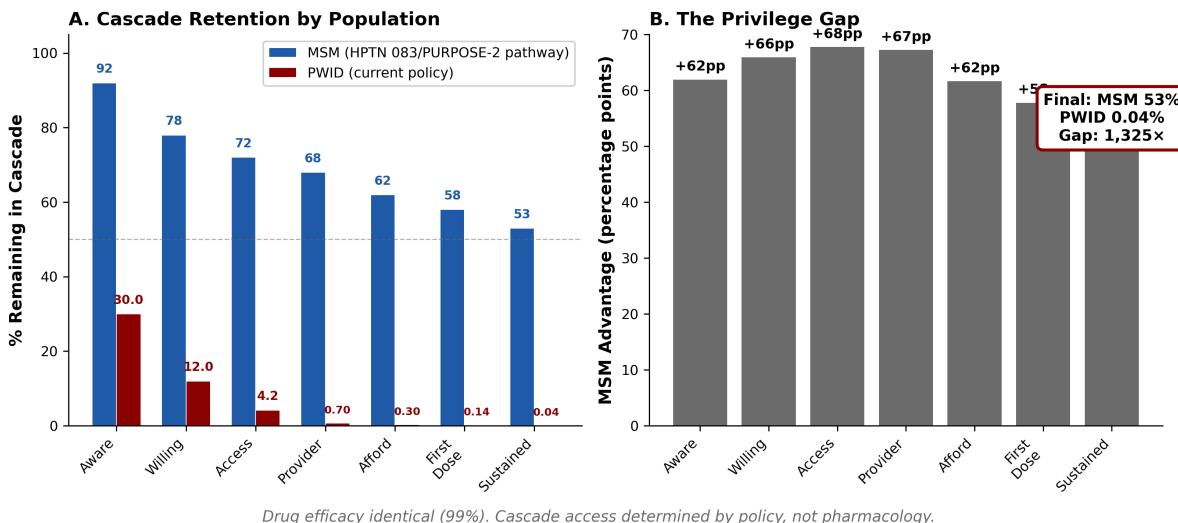

Figure 3: **Same drug, different bodies: the cascade inequality.** (A) MSM (HPTN 083/PURPOSE-2 pathway): 53% retention. PWID (current policy): 0.04%. (B) Privilege gap at each step. Final difference: 1,325-fold. Drug efficacy identical.

exists to achieve this solution:

by policy that closes every biomedical pathway to the only solvable equation.

- PEP: The 12–24 hour window for parenteral exposure is unachievable

Policy can change. The mathematics cannot.

- PrEP: No FDA approval, failed implementation science, 0.04% cascade completion

Declarations

Contributors: ACD conceived the study, developed the model, conducted analysis, and wrote the manuscript.

Declaration of interests: ACD was previously employed by Gilead Sciences, Inc. This manuscript was developed independently. No other conflicts declared.

Data sharing: Simulation code available at [repository] upon publication.

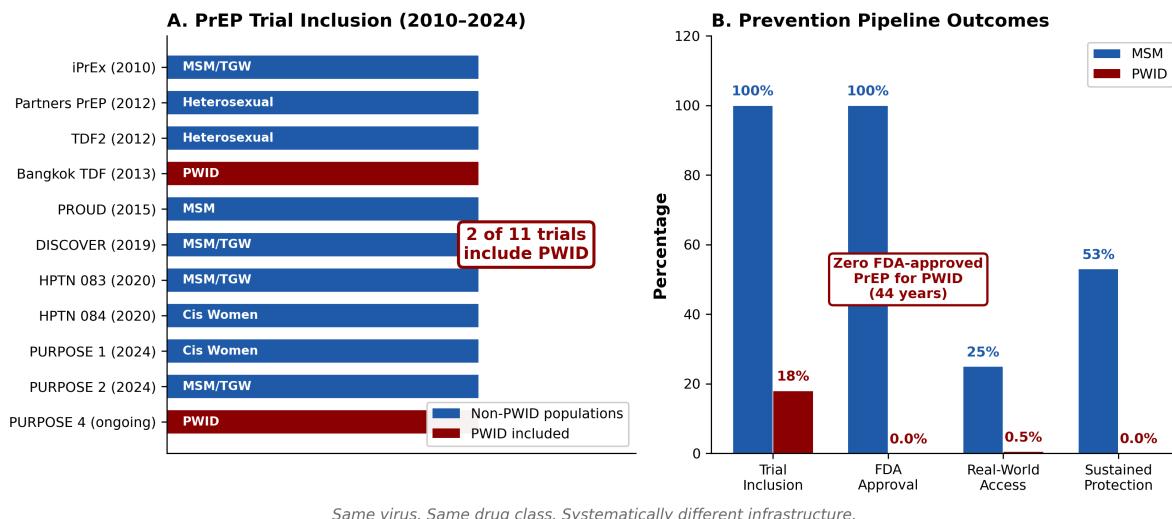

Figure 4. Systematic Exclusion: 44 Years of Differential Access

Figure 4: Systematic exclusion: 44 years of differential access. (A) Trial inclusion: 2/11 include PWID. (B) Pipeline outcomes: MSM achieve 100% FDA approval; PWID achieve 0%. Same virus, same drug class, systematically different infrastructure.

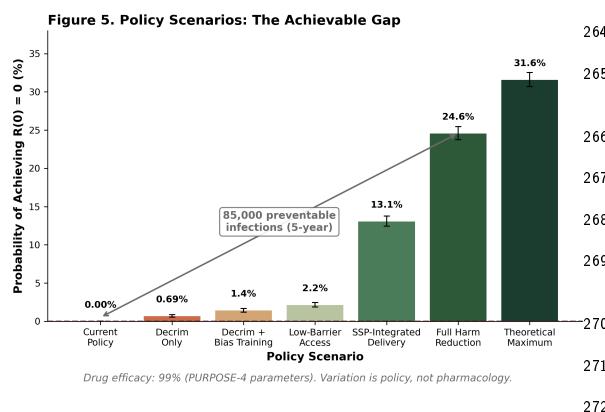

Figure 5: Policy scenarios: the achievable gap. Current policy: 0.00%. Full harm reduction: 24.59%. The 85,000 preventable infections over 5 years represent policy choice, not epidemic dynamics.

259 **Funding:** None.
